## **Cheat Sheet: API's and Data Collection**

Package/Method	Description	Code Example
Accessing element attribute	Access the value of a specific attribute of an HTML element.	<pre>Syntax:     attribute = element[(attribute)]  Example:     href = link_element[(href)]</pre>
BeautifulSoup()	Parse the HTML content of a web page using BeautifulSoup. The parser type can vary based on the project.	Syntax:  soup = BeautifulSoup(html, (html.parser))  Example:  html = (https://api.example.com/data) soup = BeautifulSoup(html, (html.parser))
delete()	Send a DELETE request to remove data or a resource from the server. DELETE requests delete a specified resource on the server.	Syntax:     response = requests.delete(url)  Example:     response = requests.delete((https://api.example.com/delete))
find()	Find the first HTML element that matches the	<pre>Syntax:     element = soup.find(tag, attrs)</pre>

about:blank 1/6

<i>-</i> 11.	27/23, 3.40 I WI		about.biank
		specified tag and attributes.	<pre>Example:     first_link = soup.find((a), {(class): (link)})</pre>
	find_all()	Find all HTML elements that match the specified tag and attributes.	<pre>Syntax:     elements = soup.find_all(tag, attrs)  Example:     all_links = soup.find_all((a), {(class): (link)})</pre>
	findChildren()	Find all child elements of an HTML element.	<pre>Syntax:     children = element.findChildren()  Example:     child_elements = parent_div.findChildren()</pre>
	get()	Perform a GET request to retrieve data from a specified URL. GET requests are typically used for reading data from an API. The response variable will contain the server's response, which you can	<pre>Syntax:     response = requests.get(url)  Example:     response = requests.get((https://api.example.com/data))</pre>

29/25, 5:48 PM		about:blank
	process further.	
Headers	Include custom headers in the request. Headers can provide additional information to the server, such as authentication tokens or content types.	Syntax:  headers = {(HeaderName): (Value)}  Example:  base_url = (https://api.example.com/data) headers = {(Authorization): (Bearer YOUR_TOKEN)} response = re
Import Libraries	Import the necessary Python libraries for web scraping.	Syntax:  from bs4 import BeautifulSoup
json()	Parse JSON data from the response. This extracts and works with the data returned by the API. The response.json() method converts the JSON response into a Python data structure (usually a dictionary or list).	<pre>Syntax:     data = response.json()  Example:     response = requests.get((https://api.example.com/data))     data = response.json()</pre>
next_sibling()	Find the next sibling element in the DOM.	<pre>Syntax:     sibling = element.find_next_sibling()  Example:</pre>

3/29/25, 5:48 PM about:blank

```
next_sibling = current_element.find_next_sibling()
                                  Syntax:
                                       parent = element.parent
                  Access the
                  parent element
                  in the
parent
                  Document
                                  Example:
                  Object Model
                  (DOM).
                                       parent_div = paragraph.parent
                                  Syntax:
                                        response = requests.post(url, data)
                  Send a POST
                  request to a
                  specified URL
                  with data.
                  Create or
                  update POST
                  requests using
                  resources on
post()
                                  Example:
                  the server. The
                  data parameter
                                        response = requests.post((https://api.example.com/submit), data={(key): (value)})
                  contains the
                  data to send to
                  the server,
                  often in JSON
                  format.
                                        response = requests.put(url, data)
                  Send a PUT
                  request to
                  update data on
                  the server.
                  PUT requests
                  are used to
                  update an
                  existing
put()
                  resource on
                                  Example:
                  the server with
                  the data
                                        response = requests.put((https://api.example.com/update), data={(key): (value)})
                  provided in the
                  data
                  parameter,
                  typically in
                  JSON format.
```

about:blank 4/6

```
Syntax:
                                               params = {(param_name): (value)}
                      Pass query
                      parameters in
                      the URL to
                      filter or
                      customize the
Query parameters
                      request. Query
                                         Example:
                      parameters
                                                base_url = "https://api.example.com/data"
params = {"page": 1, "per_page": 10}
response = requests.get(base_url, params=params)
                      specify
                      conditions or
                      limits for the
                      requested data.
                                         Syntax:
                                                element = soup.select(selector)
                      Select HTML
                      elements from
select()
                      the parsed
                      HTML using a
                                         Example:
                      CSS selector.
                                                titles = soup.select((h1))
                                         Syntax:
                                                response.status_code
                      Check the
                      HTTP status
                      code of the
                      response. The
                      HTTP status
                      code indicates
                      the result of
                      the request
status_code
                      (success, error,
                                         Example:
                      redirection).
                      Use the HTTP
                                                url = "https://api.example.com/data"
                                                response = requests.get(url)
                      status codeIt
                                                status_code = response.status_code
                      can be used for
                      error handling
                      and decision-
                      making in
                      your code.
tags for find()
                      Specify any
                                         Tag Example:
and find_all()
                      valid HTML
                                                - (a): Find anchor () tags.
                      tag as the tag
                                               - (a). Ind ancient (7 cags.
- (p): Find paragraph ((p)) tags.
- (h1), (h2), (h3), (h4), (h5), (h6): Find heading tags from level 1 to 6 ( (h1),n (h2)).
- (table): Find table () tags.
- (tr): Find table row () tags.
                      parameter to
                      search for
                      elements of
                                                - (td): Find table cell ((td)) tags.
                      that type. Here
```
